

PhD Candidate Profile

Name:

Géssica de Oliveira Santiago Santos

**Research Group (if relevant):**

Grupo de eletroquímica e nanotecnologia - ITP

Grupo de Investigación en Tecnología Química y Medioambiental - ITQUIMA

Research Centre (if relevant):

Instituto de Tecnologia e Pesquisa (ITP)

Instituto de Tecnología Química y Medioambiental (ITQUIMA)

Department/School(s) (if relevant):

N/A

College:

Universidade Tiradentes

Universidad Castilla-La Mancha

Supervisor(s):

Manuel Andrés Rodrigo Rodrigo

Giancarlo Richard Salazar Banda

Katlin Ivon Barrios Eguiluz

Funding body:

Financial support from the Spanish Ministry of Economy, Industry and Competitiveness and European Union through project CTM2016-76197-R (AEI/FEDER, UE).

Brazilian agencies CAPES for the scholarship awarded.

Area (field) of study:

Electrochemical oxidation of organic compounds

Thesis Title:

Laser synthesis of mixed metal oxides anodes applied to the degradation of organic compounds

Abstract:

The use of agrotoxics in order to improve agricultural production has increased considerably due to the high demand for food resulting from the growth of the world population, which has led to a problem of contamination in the environment with these agrochemicals. Among these contaminants found in washing waters are organochlorine compounds that are persistent in the environment and bioaccumulative in the food chain, causing several adverse effects on human health and ecosystems. Thus, due to their high stability, presenting extreme resistance to physical, chemical and biological removal, the direct use of

PhD Candidate Profile

conventional treatments in order to decontaminate these effluents is not recommended. In order to overcome this problem, environmental remediation proposals have been focus of studies.

Alternative process has been developed to treat effluents containing organochlorines based on the use of advanced oxidation process (AOP), based on the generation of hydroxyl radicals, a powerful oxidizing agent that appears as a promising alternative for the treatment of organic substances with difficult degradation. Among the AOPs, electrochemical oxidation has gained considerable attention since it can be used as a pre-treatment, it occupies a significantly smaller area in comparison to other remediation processes and alone it can completely decompose organic pollutant. In this manner, electrochemical oxidation processes appear to be a clean and efficient technology for effluent treatment and present total environmental compatibility since, at the end of the process, organic compounds are reduced to CO₂ and H₂O.

On the other hand, recent studies have shown that the efficiency of electrochemical processes can be enhanced by combining two or more POAs, such as the application of ultraviolet (UV) radiation, due to the increase in the generation of oxidizing species and the better activation of these species. Thus, the present proposal is based on the study of the applicability of the photoelectrochemical process for the degradation of organochlorines, in order to optimize and analyze the degradation pathways with the use of two types of anodes (i.e., Ti/Ru_{0.3}Ti_{0.7}O₂ and boron doped diamond anodes), for comparative purposes. The Ti/Ru_{0.3}Ti_{0.7}O₂ anodes synthesized according to a low cost alternative methodology using CO₂ laser.
